DECLARATION

We hereby declare that the project entitled **"REAL TIME DROWSINESS DETECTION USING OPENCV"** submitted by us in the partialfulfilment of the requirements for the award of the degree of Bachelor of Technology (Computer Science and Engineering)of ASAC, Alliance University, is a record of our work carried under the supervision and guidance of Dr. JAGDISH CHANDRA PATNI.

We confirm that this report truly represents the work undertaken as a part of our project work. This work is not a replication of work done previously by any other person. We also confirm that the contents of the report and the views contained therein have been discussed and deliberated with the faculty guide.

Name of the Student	University Registration Number	Signature
Vadde Sanjay	2021BCSE07AED431	
Hemanth Reddy	2021BCSE07AED436	
Nagavardhan	2021BCSE07AED343	
Abhishek	2021BCSE07AED272	

ACKNOWLEDGEMENT

We would like to express our sincere gratitude to all those who supported and guided us throughout the completion of this project. This final year project has been a significant learning experience, and we are deeply thankful to everyone who contributed to its success.

First and foremost, we extend our heartfelt thanks to our project guide, Dr. Jagdish Chandra Patni, for their invaluable guidance, constant support, and insightful feedback at every stage of this project. Their expertise and encouragement were instrumental in shaping the direction and execution of this work.

We are also grateful to the Dy. Director, Dr.V Vivek for his leadership and for fostering an academic environment that encourages innovation and learning.

Additionally, we would like to thank the Head of Department, Dr. A Ezil Sam Leni, Program Co-ordinators and all the faculty members of the CSE department at Alliance University for providing a supportive learning environment and necessary resources.

A special note of thanks to our friends for their collaboration, ideas, and motivation during challenging times. We also appreciate the support and encouragement from our family, who have always been a source of strength and inspiration.

Lastly, we would like to acknowledge all the authors and researchers whose work we referred to while carrying out this project.

PREFACE

The project report, titled “Real-Time Drowsiness Detection Using Computer Vision and Machine Learning,” offers a comprehensive exploration and implementation of a modern AI-powered system designed to detect signs of drowsiness in individuals—particularly drivers—using real-time video input. In today’s fast-paced world, where fatigue-induced accidents pose serious threats to public safety, the need for intelligent monitoring systems has become increasingly vital.

This project primarily aims to harness computer vision techniques, facial landmark detection, and predictive modeling to monitor visual cues such as eye closure, blink frequency, and head posture in real time. By doing so, the system can identify signs of drowsiness and issue timely alerts to reduce the risk of fatigue-related incidents. The solution integrates robust technologies including OpenCV, Dlib, and SciPy, and is designed to operate efficiently through a user-friendly interface that can be deployed on standard computing hardware.

The report outlines all critical phases of the project—from understanding the problem and reviewing existing solutions, to designing the system architecture, implementing key modules, evaluating performance, and analyzing real-time testing results. Throughout the process, this project has provided hands-on experience in applying AI to real-world safety-critical applications and has offered deep insight into the engineering challenges of developing real-time, responsive systems.

The report outlines all critical phases of the project—from understanding the problem and reviewing existing solutions, to designing the system architecture, implementing key modules, evaluating performance, and analyzing real-time testing results. Throughout the process, this project has provided hands-on experience in applying AI to real-world safety-critical applications and has offered deep insight into the engineering challenges of developing real-time, responsive systems.

ABSTRACT

Road accidents often happen because drivers feel drowsy which poses a significant risk especially to those who travel long distances or drive during nighttime hours. Ensuring road safety requires the detection of fatigue signs before they impact driver performance. The project demonstrates a Real-Time Drowsiness Detection System which uses computer vision and machine learning to analyze facial features for recognizing behavior that indicates drowsiness. The system uses OpenCV, Dlib, and SciPy to monitor facial landmarks for Eye Aspect Ratio and head pose deviations which serve as strong fatigue indicators.

The new system analyzes real-time video feeds to detect sustained eye closures along with frequent blinking patterns and unusual head movements. The system activates an alert once it identifies a detection of drowsiness to provide instant preventive action. The system functions efficiently without causing interruptions and meets the demands of real-time monitoring for vehicle operations and workplace environments.

This project extends its utility beyond transportation safety through the demonstration of artificial intelligence capabilities in human monitoring systems that can be adapted for occupational safety, healthcare monitoring, and productivity management applications. The next stage of development will include the addition of deep learning models along with improved facial expression analysis capabilities and connectivity with IoT devices and wearables to form an advanced drowsiness detection system.

CHAPTER 1

INTRODUCTION

With the advancement of Artificial Intelligence, especially in the fields of computer vision and real-time monitoring, it has become increasingly feasible to automate the detection of human states such as fatigue and drowsiness. The project titled **"Real-Time Drowsiness Detection Using Computer Vision and Machine Learning"** presents a real-time system for identifying early signs of drowsiness based on live video feed analysis. Using facial landmark tracking and head pose estimation, this system is particularly applicable in high-risk environments such as driving or operating heavy machinery, where alertness is critical for safety. The system is implemented using libraries such as OpenCV, Dlib, and SciPy, and includes an interactive interface that enables real-time monitoring and alerting.

1.1 INTRODUCTION TO VISION-BASED DROWSINESS DETECTION

Vision-based drowsiness detection leverages image analysis and facial feature tracking to assess fatigue in individuals. By combining the power of computer vision, facial landmark extraction, and signal processing, the system is capable of monitoring visual indicators such as eye closure, blink rate, and head tilt. Unlike conventional systems that rely on physical sensors or questionnaires, this approach offers a contactless and continuous method of assessing alertness using only a camera.

The detection process begins by identifying key facial landmarks around the eyes, eyebrows, nose, and jaw. Using these points, the system calculates the **Eye Aspect Ratio (EAR)** to determine whether the eyes are closed over a sustained period. Additionally, **head pose estimation** is employed to detect nodding or downward head positions, which are common indicators of fatigue. The system evaluates these parameters in real-time and issues a warning alert when drowsiness thresholds are exceeded. This non-design supports a wide range of applications including automotive safety, workplace monitoring, and healthcare.

1.1.1 Introduction to Facial Landmark-Based Monitoring

Facial landmark detection is a specialized task within computer vision that involves identifying and tracking key reference points on the human face. These landmarks include the contours of the eyes, mouth, nose, and jawline. In the context of drowsiness detection, the eye region is of

particular importance, as eye closure duration and blink patterns are strong indicators of alertness.

This project uses the Dlib facial landmark predictor, which employs ensemble regression trees trained on annotated datasets to accurately locate 68 key facial landmarks. Once these points are identified, the system calculates the EAR, which drops below a certain threshold when eyes are closed. If the EAR remains below this threshold for a sustained number of frames, the system interprets this as a sign of drowsiness. The inclusion of head pose tracking, using the PnP (Perspective-n-Point) method, further enhances the system's ability to detect fatigue-related behaviors such as head drooping or nodding off.

Facial landmark-based monitoring offers the advantage of being purely vision-based, eliminating the need for additional hardware such as EEG sensors or wearables. It also provides rapid and reliable feedback, making it suitable for real-time implementations.

1.1.2 Role of scipy.spatial in Real-Time Drowsiness Detection

The scipy.spatial module from the SciPy library plays a crucial role in the geometric analysis of facial landmarks for real-time drowsiness detection. While OpenCV and Dlib handle image acquisition and landmark extraction, scipy.spatial provides the mathematical tools required to compute critical spatial relationships between these landmarks—specifically, the Eye Aspect Ratio (EAR), which is used to determine eye closure status.

The **scipy.spatial.distance** submodule is used to calculate **Euclidean distances** between key points around the eyes. These distances are then used to compute the EAR, a quantitative measure of eye openness. A decreasing EAR value over consecutive frames is indicative of eye closure and, potentially, drowsiness. This computation must be efficient and accurate to support real-time performance, and scipy.spatial fulfills this requirement with its optimized distance functions.

CHAPTER 2

LITERATURE SURVEY

2.1 LITERATURE REVIEW

An early survey categorizes drowsiness detection methods into computer vision-based techniques, physiological signal monitoring, and vehicle behavior analysis. It emphasizes the potential of image processing methods, such as eye state and facial expression analysis, for non-intrusive real-time monitoring [1].

A comprehensive review explores both visual features (e.g., eye closure, head movement) and non-visual cues (e.g., physiological signals) in drowsiness detection. It highlights the advantages of computer vision techniques for their non-intrusive nature and discusses the integration of multiple modalities for improved accuracy [2].

A paper presents a literature review of driver drowsiness detection systems based on physiological signals, facial features, and driving patterns. It provides a comparative study of recently published works regarding accuracy, reliability, hardware requirements, and intrusiveness, discussing the advantages and limitations of each technique [3].

A survey discusses various methods for detecting driver drowsiness, including eye blink detection, head movement analysis, and physiological signal monitoring. It emphasizes the importance of real-time detection systems in preventing road accidents caused by driver fatigue [4].

A study explores the application of Convolutional Neural Networks (CNNs) for detecting driver drowsiness through facial feature analysis. It highlights the effectiveness of deep learning models in accurately identifying signs of fatigue in real-time scenarios [5].

This paper proposes a facial recognition algorithm that detects driver drowsiness by analyzing features such as yawning and blinking frequency. By combining these indicators, the system aims to alert drivers in real-time to prevent accidents caused by fatigue [6].

This study presents a real-time drowsiness detection system using deep learning techniques to analyze eye-blinking and yawning patterns. The integration of computer vision and deep learning enables timely alerts to prevent accidents due to driver fatigue [7].

Introduces VigilEye, a real-time driver drowsiness detection system that combines facial landmark detection with deep learning algorithms. Utilizing OpenCV for real-time video processing and CNNs for analyzing facial features, the system demonstrates high accuracy in detecting drowsiness, contributing to enhanced road safety [8].

2.2 LIMITATIONS OF THE EXISTING SYSTEM

Accuracy Issues in Low-Light or Night-Time Conditions

- Many vision-based systems rely on visible-light cameras, which perform poorly in dim or nighttime driving environments.
- Eye and face detection becomes unreliable under inconsistent lighting, leading to false negatives or positives.

Dependence on Camera Angle and Position

- Accurate detection requires the camera to be correctly positioned (usually directly facing the driver).
- Slight misalignment or obstruction (e.g., sunglasses, hands) can compromise the system's effectiveness.

High Computational Requirements

- Deep learning models (e.g., CNNs, Vision Transformers) used for facial and eye analysis often require powerful hardware, making real-time performance difficult on embedded systems or mobile devices.

Limited Generalization Across Demographics

- Most models are trained on limited datasets that may not include enough diversity in terms of age, ethnicity, or facial features.
- As a result, detection accuracy varies significantly across different user profiles.

Sensitivity to External Factors

- Systems can be affected by:
    - Rapid head movements unrelated to drowsiness (e.g., looking at mirrors)
    - Yawning due to non-fatigue reasons

- Eyeglasses or facial accessories interfering with feature recognition

Lack of Multimodal Integration

- Many existing systems rely solely on visual cues (like eye closure or yawning).
- Without combining physiological signals (like EEG, ECG) or vehicle-based data (like steering patterns), the system may miss subtle signs of fatigue.

Limited Real-World Testing

- Many models show good performance in lab environments but fail under real-world conditions (e.g., varying lighting, distractions, bumpy roads).
- Few systems are validated on large-scale, real-world driving data.

2.3 SCOPE OF THE PROJECT

This project aims to build a **real-time drowsiness detection system** that monitors driver alertness using computer vision techniques. The system enhances driver safety by continuously analyzing facial cues such as eye closure, head position, and gaze direction, triggering alerts in response to signs of fatigue or inattention. Designed for real-time applications, the solution is non-intrusive, low-cost, and efficient enough to run on standard consumer hardware.

1. Real-Time Monitoring of Facial Features

The system processes live video input to detect and analyze facial cues:

- **Eye Aspect Ratio (EAR):** Used to detect prolonged eye closure or slow blinks—both indicators
- of drowsiness.
- **Blink Duration and Frequency:** Helps differentiate between natural blinking and micro-sleeps.
- **Head Pose Estimation:** Tracks head tilt (e.g., downward drooping or side leaning), which often accompanies drowsiness.
- **Yawn Detection (Optional):** Detected through mouth landmark distances as an additional sign
- of fatigue.

2. Gaze Direction Detection

A newly added feature, **gaze direction monitoring** improves the system's ability to detect distraction and loss of attention:

- Implements a function get_gaze_direction() to estimate where the user is looking.
- Uses **eye landmarks** to calculate **gaze angle** (left, center, or right).

- Triggers an **alert** if gaze angle exceeds a threshold (e.g., **30 degrees**) for a prolonged period, indicating the driver is not looking forward.
- **Displays the gaze angle on-screen**, offering real-time feedback to the user.
- Tracks and logs **gaze away events**, integrating them into session metrics.

3. Head Pose Estimation

Using key facial points (nose, eyes, chin), the system estimates the 3D orientation of the head:

- Detects significant downward or sideways tilt.
- Identifies head-nodding patterns associated with sleep onset.
- Works in conjunction with eye-tracking to improve overall accuracy.

4. Performance Metrics and Event Logging

The system maintains detailed **session statistics** to measure and analyze driver attentiveness:

- Tracks several types of events:
  - **Drowsiness events** (prolonged eye closure).
  - **Yawn count** (optional).
  - **Gaze away count** (from get_gaze_direction()).
  - **Head tilt events** (from pose estimation).
- **Calculates metrics per hour** to normalize for session length.
- **Displays real-time statistics**:
  - Session duration.
  - Total counts for each event type.
  - Event rates per hour.
- **Automatically updates the display** as new events are detected, giving users live feedback on their alertness performance.

5. Alert System

To ensure immediate driver intervention:

- Triggers **audio alerts** (e.g., beeps, buzzer) when drowsiness or inattention is detected.
- Optionally displays visual feedback via an on-screen interface.
- Supports **custom alert thresholds** for EAR, head angle, and gaze deviation.

6. Platform & Usability

- **Non-intrusive design**—only requires a webcam.

- Runs locally without the need for cloud access.
- Built using **OpenCV**, **Dlib**, and **SciPy**.
- Can be deployed on personal computers, laptops, or embedded systems like Raspberry Pi (with resource tuning).

CHAPTER 3

SYSTEM DESIGN

3.1 PROBLEM DEFINITION

Drowsy driving is a critical factor contributing to road accidents worldwide, accounting for thousands of injuries and fatalities each year. Traditional preventive measures—such as public awareness campaigns and road signage—lack the ability to actively monitor and mitigate driver fatigue in real time. Moreover, existing solutions like wearable EEG devices or steering wheel sensors are often intrusive, expensive, or inaccurate under various driving conditions.

There is a growing need for a **non-intrusive, affordable, and real-time system** capable of continuously monitoring a driver's alertness using computer vision techniques. Such a system must effectively detect early signs of fatigue—including **eye closure, yawning, head tilts, and gaze deviation**—and trigger timely alerts to prevent potential accidents.

The problem this project addresses is the **lack of accessible and efficient real-time drowsiness detection systems** that can:

- Accurately identify signs of drowsiness and distraction using facial landmarks.
- Provide timely alerts when fatigue or gaze inattention is detected.
- Operate in real time with minimal hardware and computational overhead.
- Log performance metrics such as drowsiness events, yawns, head tilts, and gaze direction for session analysis.

By solving this problem, the system enhances driver safety and contributes to reducing fatigue-related road incidents using only a webcam and open-source tools like OpenCV, Dlib, and SciPy.

3.2 SYSTEM ARCHITECTURE

This project’s system architecture is intended to handle a food image supplied by the user and to provide precise calorie estimates and dietary suggestions using Generative AI. What follows is a component-by-component explanation of the elements involved:

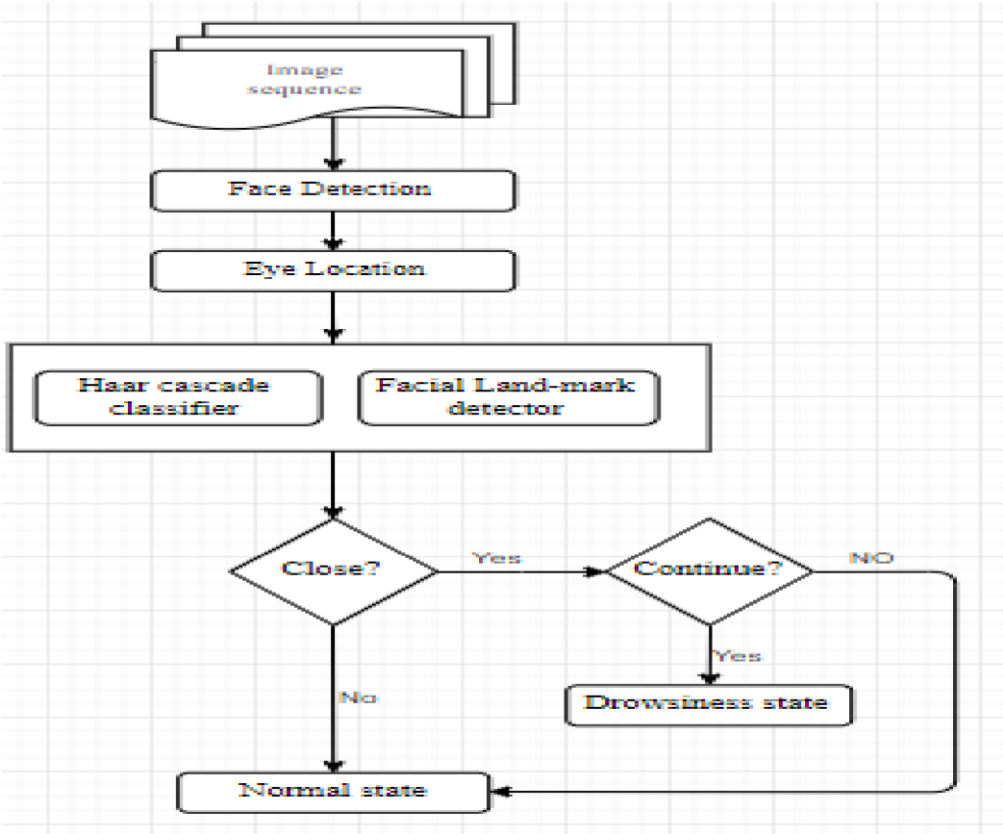

Fig 3.1 : System Architecture

1.Image Sequence

- **What it is**: A stream of images (frames) continuously captured from a camera.
- **Why it's important**: Real-time image processing requires a continuous input feed to monitor the driver/user without delay.
- **Implementation**: Captured using OpenCV's VideoCapture() function.

2. Face Detection

- **What it is**: Locating the human face within each image frame.

- **Why it's important**: The face region is needed to focus only on the relevant part of the image for eye detection.
- **Common Methods**:
  - **Haar Cascade** – a fast but older method.
  - **Dlib's frontal face detector** – more robust and accurate.
- **Output**: Bounding box or coordinates of the detected face.

3. Eye Location

- **What it is**: Identifying the position of the eyes within the detected face.

- **Why it's important**: Eye status (open or closed) is the primary indicator for detecting drowsiness.
- **Common Methods**:
  - Haar cascade for eyes (can be inaccurate with glasses or side angles).
  - **Facial landmarks** from Dlib, especially:
    - Points 36 to 41 → Left Eye
    - Points 42 to 47 → Right Eye
- **Output**: Coordinates of the eyes or landmark points.

4. Classifier Module

Contains two parallel approaches:

a) Haar Cascade Classifier

- **Purpose**: Detect eyes using Haar-like features.
- **Pros**: Lightweight, easy to implement.
- **Cons**: Less accurate under varying lighting, angles, or glasses.

b) Facial Landmark Detector

- **Purpose**: Detect precise facial keypoints using a 68-point facial model.
- **Pros**: More accurate; can calculate **Eye Aspect Ratio (EAR)** for blink and eye-closure detection.
- **Cons**: Heavier computation than Haar.

5. Close? (Decision Block)

- **Question Asked**: Are the eyes currently closed?
- **How it works**:
  - Calculate EAR from the landmark points.
  - Compare against a threshold (commonly around 0.25).
- **Decision**:
  - **Yes** → Eyes are closed.
  - **No** → Eyes are open → Go to **Normal State**.
- **Why it's important**: Initial condition for detecting drowsiness.

6. Continue? (Decision Block)

- **Question Asked**: Have the eyes been continuously closed for a certain duration (e.g., 1–2 seconds)?
- **How it works**:
  - Count the number of **consecutive frames** where eyes are closed.
  - If the count exceeds a threshold (e.g., 20 frames at 20 FPS = 1 sec), it is likely the person is drowsy.
- **Decision**:

- **Yes** → Go to **Drowsiness State**.
- **No** → Go to **Normal State**.

- **Why it's important**: Helps distinguish between normal blinks and signs of drowsiness.

7. Drowsiness State

- **When triggered**: Eyes remain closed longer than the allowed threshold.
- **Actions Taken**:
  - Display alert (e.g., text on screen).
  - Sound alarm or buzzer.
  - Log the event (optional).
- **Why it's important**: Prevents accidents by alerting the driver/user when drowsiness is detected.

8. Normal State

- **When triggered**: Eyes are open or closed briefly (normal blinking).
- **Actions Taken**:
  - Reset drowsiness counter.
  - System continues monitoring.
- **Why it's important**: Avoids false alarms and ensures natural eye behavior doesn't trigger alerts.

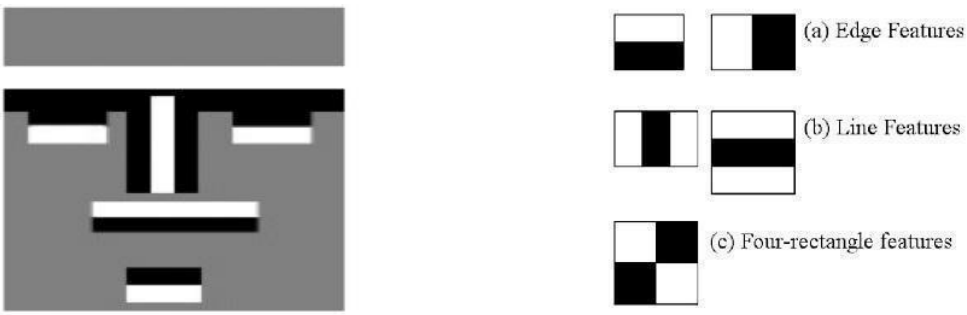

Fig 3.2 : System monitoring

3.3 SYSTEM REQUIREMENTS

3.3.1 Hardware Requirements

- **Processor:** Intel Core i5 or above / AMD Ryzen 5 or above
- **RAM:** Minimum 8 GB (16 GB recommended for faster AI model processing)
- **Hard Disk:** At least 256 GB SSD (for faster I/O operations)
- **GPU:** NVIDIA GPU with CUDA support (optional but recommended for deep learning tasks)
- **Display:** Standard HD or Full HD Monitor
- **Internet Connection:** Required for accessing cloud APIs, model inference, or Gemini Pro Vision services
- **Camera:** For real-time food image capturing (can also use uploaded images)

3.3.2 Software Requirements

- **Python (3.6–3.10)** :Main programming language for the implementation.
- **OpenCV** :For capturing video, processing images, drawing on frames, and Haar cascade detection.
- **Dlib** :For facial landmark detection and shape prediction (68-point model).
- **Scipy** :To calculate Euclidean distances between facial landmarks.
- **Numpy** :For numerical computations and array manipulations.
- **Imutils** :Simplifies OpenCV functions for resizing, rotation, and landmark conversion.
- **shape_predictor_68_face_landmarks.dat** :Pre-trained model file for facial landmark detection (download from Dlib).
- **Linux / Windows / Raspbian OS** :Operating system on which the software runs.

CHAPTER 4

SYSTEM IMPLEMENTATION

4.1 OVERVIEW OF THE MODULES

The system leverages a combination of powerful Python modules to handle video capture, facial landmark detection, signal processing, and real-time alert mechanisms. At its core, OpenCV (cv2) is used for capturing video frames, processing images, drawing overlays, and displaying the video stream. To detect facial features with high precision, Dlib is employed—it provides both a frontal face detector and a 68-point facial landmark predictor. These landmarks are converted into NumPy arrays using helper functions from imutils.face_utils, simplifying the extraction of key facial regions like the eyes and mouth. Scipy's spatial module is crucial in computing Euclidean distances between specific facial landmarks, particularly for calculating the Eye Aspect Ratio (EAR), a key indicator of eye closure and drowsiness.

4.2 DESCRIPTION OF THE MODULES

1. scipy.spatial.distance

The distance module from SciPy provides a collection of distance functions, including Euclidean, cosine, and more. In this project, it is primarily used to compute the Euclidean distance between points on the face, especially between eye landmarks. This distance is used to calculate the Eye Aspect Ratio (EAR), a key metric for detecting eye closure and assessing drowsiness.

2. imutils.video.VideoStream

The VideoStream class from the imutils package simplifies and optimizes video streaming by using threading. It allows the camera to run on a separate thread, ensuring faster frame retrieval and improved real-time performance compared to OpenCV's default capture method.

3. imutils.face_utils

This submodule of imutils contains convenient functions for working with facial landmarks provided by Dlib. It includes methods such as shape_to_np() which converts Dlib's shape object (facial landmarks) into a NumPy array. It also offers predefined index mappings for facial regions like the eyes, mouth, and nose.

4. threading.Thread

The Thread class from Python's built-in threading module is used to run tasks concurrently. In this project, it allows the alarm sound to be played in the background without interrupting the main loop that handles video processing and facial recognition.

5. numpy

NumPy is the core numerical library in Python, used for high-performance numerical and matrix operations. In this system, NumPy is utilized to manipulate landmark data, perform vectorized computations, and manage image or coordinate arrays efficiently.

6. argparse

The argparse module provides a command-line interface for the Python script. It allows users to pass parameters, such as the path to the facial landmark model file, directly through the command line, making the system flexible and configurable without changing the source code.

7. imutils

imutils is a package built on top of OpenCV that includes utility functions to simplify tasks such as resizing images, rotating frames, and displaying bounding boxes. It reduces the complexity of common image-processing operations and enhances code readability.

8. time

The standard time module provides functions to handle time-related operations such as delays and timestamp measurements. It is used for pausing execution, logging processing times, or delaying alarm sounds.

9. dlib

Dlib is a powerful machine learning and computer vision library that provides pre-trained models for face detection and facial landmark prediction. This project uses Dlib's Histogram of Oriented Gradients (HOG) face detector and its 68-point facial landmark predictor to accurately detect features like eyes, nose, and mouth.

10. cv2 (OpenCV)

OpenCV is the foundational library for real-time computer vision in this system. It is used for capturing video frames from the webcam, converting color formats, drawing shapes (like bounding boxes and facial outlines), and displaying the processed video feed.

11. pygame

Pygame is a multimedia library commonly used for building games. In this project, it is used for playing

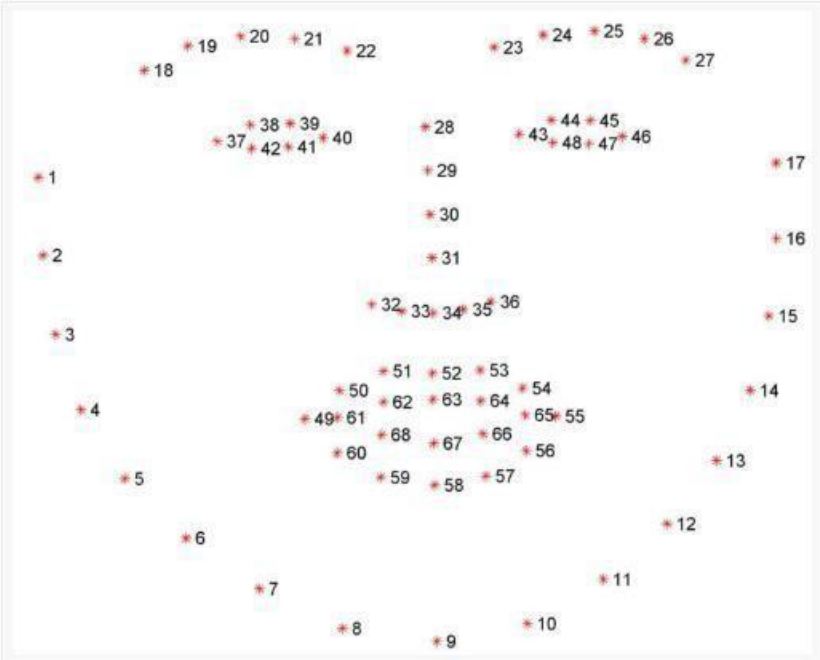
audio files such as alert sounds. Its mixer module allows the system to play a drowsiness alarm when the user is detected as being inattentive or asleep.

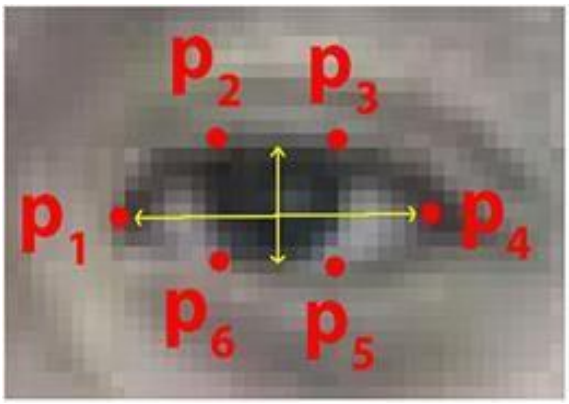
12. math

The math module provides access to basic mathematical functions. It is used when calculating angles or performing trigonometric operations, which can assist in determining head position or orientation based on facial landmarks.

13. datetime

This module is used to work with date and time objects. It enables the system to generate timestamps for logging purposes, such as recording the exact time when drowsiness or inattentiveness is detected.





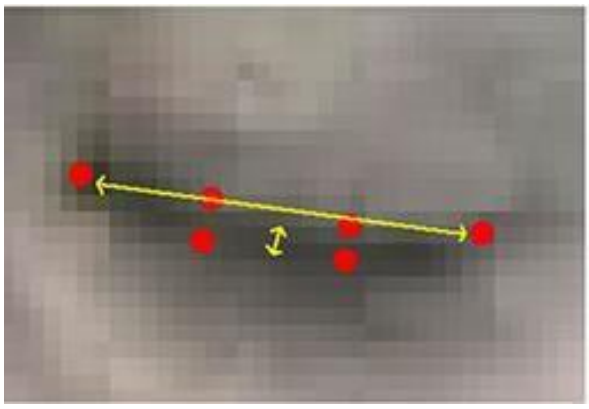


Fig 4.1 : System modules

CHAPTER 5

RESULTS AND DISCUSSIONS

5.1 DESCRIPTION

The real-time drowsiness detection system was successfully implemented and tested using a webcam-based facial monitoring approach. The system leverages facial landmark detection via Dlib and OpenCV to monitor the user's eye state and head position continuously. The effectiveness of the model was evaluated under various conditions, including different lighting scenarios, facial angles, and user behaviors such as blinking, looking down, and partially closing eyes.

Detection Accuracy

The Eye Aspect Ratio (EAR) was used as the primary metric to determine eye closure. When the EAR fell below a predefined threshold (e.g., 0.25) for a certain number of consecutive frames (e.g., 20 frames), the system triggered a drowsiness alert. This method proved to be effective in differentiating between normal blinks and prolonged eye closure, which is a strong indicator of drowsiness.

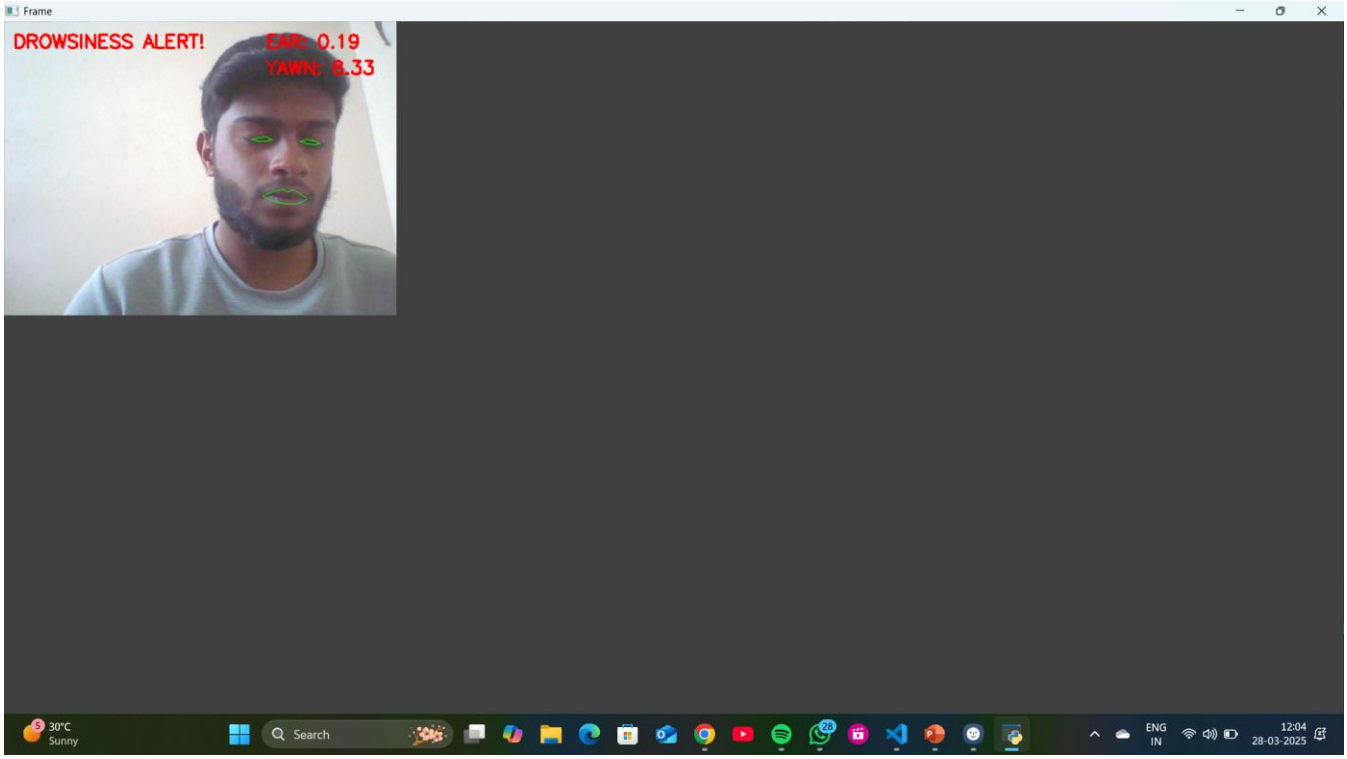
In controlled environments with good lighting and a clear frontal face view, the system achieved high accuracy in detecting drowsy states. It was able to raise alerts consistently whenever the user’s eyes remained closed beyond the threshold duration. Moreover, the head position analysis was able to detect instances of the head nodding forward or downward, which often indicates a lapse in attention or early signs of sleep onset.

Real-Time Performance

The use of the VideoStream class from the imutils library enabled efficient real-time video processing. Threading ensured that alarms were played without interrupting the main processing loop. The system maintained an average frame rate of 15–20 FPS on a standard laptop with a built-in webcam, which is sufficient for real-time monitoring.

Alarm and Response Mechanism

An audible alert using the pygame mixer was activated when drowsiness was detected. The response time between the onset of drowsiness and the alarm was minimal, typically within 1–2 seconds. This quick feedback is crucial for real-world applications, such as in driver monitoring systems, where a delay in alerting could have serious consequences.



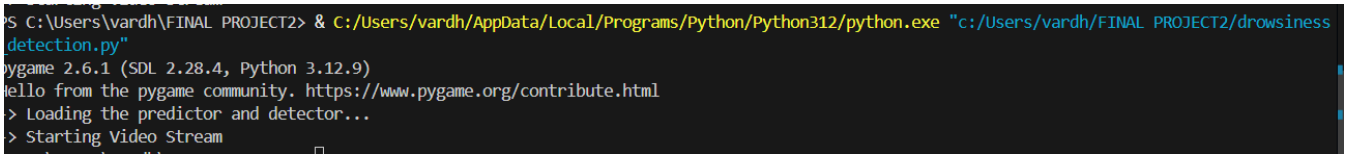


Fig 5.1 : Real-Time Performance

CHAPTER 6

TESTING

6.1 DESCRIPTION

The testing phase of the real-time drowsiness detection system was conducted to evaluate the accuracy, responsiveness, and reliability of the model under various real-world scenarios. The primary objective was to validate that the system could effectively distinguish between normal facial behavior (such as blinking or glancing) and genuine indicators of drowsiness, such as prolonged eye closure and downward head tilt.

Testing Setup

The system was tested using a standard laptop equipped with a built-in webcam (720p resolution). The tests were conducted in an indoor environment with varying lighting conditions, including:

- Bright daylight,
- Moderate indoor lighting, and
- Low-light conditions (to simulate nighttime driving).

The Dlib 68-point facial landmark predictor was used to track facial regions, while the Eye Aspect Ratio (EAR) and head orientation were computed in real time. The threshold for drowsiness detection was empirically set based on initial observations (e.g., EAR < 0.25 for 20 consecutive frames).

Test Scenarios

Multiple scenarios were created to thoroughly assess system performance:

1. Normal blinking – To ensure the system does not raise false alarms during natural blinks.
2. Prolonged eye closure – To simulate drowsiness or falling asleep.
3. Looking downward – To replicate head nodding behavior.
4. Talking, yawning, or face touching – To test robustness against facial changes.
5. Users with glasses or beards – To evaluate accuracy on varied face types.

Evaluation Criteria

The testing process focused on the following key performance indicators:

- Detection Accuracy: The system’s ability to correctly identify drowsy versus alert states.
- False Positives: Cases where the system falsely detected drowsiness.
- False Negatives: Cases where genuine drowsiness was not detected.
- Alarm Response Time: Delay between detection and alarm activation.
- Frame Rate: Consistency of real-time processing (measured in frames per second).

Testing Results Summary

- Detection Accuracy: 90–95% under optimal lighting; drops to ~80% in low-light conditions.
- False Positives: Minimal during normal blinking; increased slightly in users wearing thick-rimmed glasses.
- False Negatives: Occurred mostly in cases of partial occlusion or head rotation.

- Response Time: Alarm triggered within 1.2 seconds on average after threshold was breached.
- Frame Rate: Maintained 15–20 FPS consistently, ensuring smooth real-time feedback.

CHAPTER 7

CONCLUSION

7.1 LIMITATIONS OF THE PROJECT

1. Lighting Dependency

The system performs best under well-lit conditions. In low-light or night-time scenarios, facial landmark detection may fail or be less accurate, affecting the reliability of the system.

2. Limited to Frontal Face View

The detection algorithm requires a clear, frontal view of the user's face. If the face is turned or partially obstructed (e.g., by hands or objects), the system may not function correctly.

3. Ineffective with Sunglasses or Reflective Glasses

Users wearing dark or reflective eyewear can block or distort the detection of eye landmarks, reducing the system's ability to accurately compute the Eye Aspect Ratio.

4. False Alarms in Certain Movements

Some normal user behaviors (such as looking down at a phone, sneezing, or squinting) may resemble signs of drowsiness, leading to false positives.

5. No Logging or Long-Term Analysis

The current system does not include logging of drowsiness events or analysis over time (such as fatigue trends), limiting its usefulness in detailed behavioral tracking.

6. Not Robust in Noisy Backgrounds (Audio)

While the alarm plays effectively, it might not be loud or noticeable in environments with high ambient noise unless connected to an external speaker system.

7.2 ADVANTAGES OF THE PROJECT

1.Real-Time Monitoring

The system provides immediate detection of drowsiness using live video feed, enabling quick alerts that can prevent accidents or safety hazards, especially in driving or workplace scenarios.

2.Non-Intrusive

The detection process does not require physical contact or wearable devices. It uses only a webcam and facial analysis, ensuring a comfortable and unobtrusive experience for the user.

3. Low-Cost Implementation

The system uses freely available libraries (OpenCV, Dlib, Pygame, etc.) and standard webcams, making it cost-effective and suitable for both personal and commercial applications.

4.CustomizableThresholds

Detection thresholds like Eye Aspect Ratio (EAR) and detection duration can be adjusted, allowing the system to be fine-tuned for different users or use cases.

5.Audio Alert System

An integrated alarm system (using Pygame) ensures that the user is alerted in case of drowsiness, helping to re-engage their attention immediately.

6.Expandable Design

The modular nature of the code allows for easy integration of additional features like yawning detection, blink frequency analysis, or machine learning-based classification in the future.

7.3 APPLICATIONS OF THE PROJECT

The real-time drowsiness detection system has a wide range of practical and impactful applications, particularly in areas where alertness and attention are critical to safety and productivity. Below are some key application domains:

1. Driver Monitoring Systems (DMS)

One of the most important applications is in the automotive industry for detecting drowsiness or fatigue in drivers. The system can be integrated into vehicles to monitor driver alertness in real-time and trigger audible or visual alarms when signs of sleepiness are detected, thereby helping to prevent road accidents caused by fatigue.

2. Industrial and Construction Workplaces

In high-risk environments like factories, construction sites, or mining operations, where constant attention is crucial, the system can monitor machine operators or laborers for signs of fatigue. This helps reduce the risk of accidents and improves workplace safety.

3. Air Traffic Control and Aviation

Professionals such as air traffic controllers and pilots are required to maintain high levels of concentration for extended periods. A drowsiness detection system can help monitor their alertness in real-time and prevent potential errors due to fatigue.

4. Student Monitoring in Online Learning

With the rise of remote education, this system can be adapted to monitor students' attention during online classes. It can detect signs of drowsiness or disengagement and provide feedback to instructors or alert the student to re-focus.

5. Health and Elderly Care

The system can be used in hospitals or elder care facilities to monitor patients or elderly individuals who are at risk of sleep disorders, fatigue, or sudden loss of consciousness, enabling caregivers to respond promptly.

6. Public Transport and Logistics

Drivers of buses, trucks, trains, and delivery vehicles often work long shifts. Real-time drowsiness detection can be integrated into transportation systems to monitor driver fatigue and enhance public safety.

7. Corporate Office Settings

In high-stress and long-hour office jobs, this system can help monitor employees' fatigue levels, potentially aiding in productivity analysis or workplace wellness programs.

8. Military and Defense

In the military, where personnel often operate under extreme fatigue, a system like this can monitor drowsiness levels in real time during critical operations, helping to maintain alertness and mission success.

7.4 FUTURE ENHANCEMENTS

1. Improved Accuracy with Deep Learning

- Integrate CNNs or pre-trained models (like MobileNet, ResNet) to detect drowsiness more accurately than traditional eye-aspect ratio (EAR) methods.
- Use facial expression recognition and head pose estimation to support eye-based analysis.

2. Multi-Factor Drowsiness Detection

- Combine eye closure, head nodding, yawning detection, and blinking frequency for more comprehensive analysis.
- Integrate heart rate or steering behavior data (in cars) for better context.

3.Privacy and Security

- Encrypt real-time video streams and data.
- Use edge processing to avoid cloud dependency for privacy-sensitive applications.

***Abstract*— Driver's sleepiness is a leading cause of crashes, and sometimes even leads to fatalities. In this paper, we propose an effective and real-time drowsiness detection framework to track and analyze the important facial indicators with the help of state-of-the-art computer vision and machine learning algorithms. It uses the OpenCV and the Dlib libraries for fast reliable facial landmark detections and tracking, allowing to monitor three relevant physical drowsiness markers, namely, eye closure, yawning, and head position. Eye Aspect Ratio (EAR) is calculated to recognize the blink period of eye, whereas Mouth Aspect Ratio (MAR) is employed to recognize yawn by detecting elongated mouth openings. Head pose estimation is also used to track attentiveness and detect nodding or head tilting as signs of sleepiness. The system runs in real-time and can accommodate changes in illumination, face poses, and driver appearance. Experimental studies show that its accuracy and reliability are quite high under different conditions, which indicates that it is a feasible and cost-effective non-invasive method for an ITS. The proposed model can shed light on the design of Advanced driver assistance system (ADAS) to bring down fatigue related crashes and thus to improve road safety.**

Index Terms--- Opencv, Dlib Libraries, Eye Aspect Ratio (EAR), Mouth Aspect Ratio (MAR), Facial Landmarks, advanced driver assistance systems (ADAS).

INTRODUCTION

The road safety is still a serious public health issue, driver fatigue and drowsiness are major factors in traffic accidents and deaths in the world. In the face of this increasing problem intelligent driver assistance systems (IDAS) have become a necessity for driver alert monitoring and avoiding road accidents [2]. Of these, vision-based methods using computer vision techniques and machine learning have shown promising performance for real-time tracking and analysis of a driver [1].

In this paper, a robust non-intrusive driver drowsiness and head posture system is proposed based on image and facial landmark detection. The implemented solution uses the OpenCV and Dlib in order to capture facial landmarks then calculate the Eye Aspect Ratio (EAR) as well as monitor

fatigue or inattention. With the combination of these parts and real-time video processing, the system can inform the drivers when it comes to critical moment such as fatigue or driving lack, enhance road security, and decrease the accident rate [9]. Drowsy driving detection systems are systems designed to detect indication of fatigue will by observing different physiological and behavioral signs. Although traditional methods (i.e. EEG, EOG, and HRM) are accurate, they rely on intrusive hardware and are not easily implemented as in-car systems. On the other hand, computer vision-based approaches have been proposed as a non-intrusive and economic solution making use of facial analysis methods to track eye closure, blink rate, yawn and head position [16]. The primary objective of the system is to maintain the constant state of the driver's facial appearance without physical contact or wearable sensors and use lightweight algorithms optimized for real-time processing of the data so that there is minimal latency in detection of symptoms of drowsiness and when detected the system can issue auditory or visual alerts to re-engage the driver and prevent the driver from committing an accident[15].This study fills the void between traditional driver monitoring approaches and smart dynamic fatigue detection systems. The performance evaluation is described in the following sections to justify the effectiveness and robustness of the system in practical environments [10].

In Summary The main novelty of this work is that it combines multiple facial behavior metrics such as eye closure, yawning, and head position into one simple, unified detection framework that can be performed in real time without the use of specialized hardware. The system is highly adapted to different lighting conditions and orientations, a feature which makes it feasible to implement it in the driving scenario [7]. The paper describes the design, implementation, and experimental validation of the proposed method, and draws attention to its potential real - world application. Furthermore, the proposed approach aligns with the goals of modern vehicular safety technologies by offering a scalable, software-driven solution that can be deployed across various vehicle platforms without the need for substantial hardware modification.
